Staying in compliance with your Urologist's "compliance" aspect regarding training for rehabilitation with the [USPhysioMED Traction Device](#) is imperative for a better outcome to your PD REHABILITATION RESULTS. As stretching of the scar tissue helps in having the "traction" device do its job by bringing in more blood while enhancing an erection in the penis. This help break-up the hardened and density part where the Peyronie's Disease scar tissue is creating the angulation of the Peyronie's Disease.

All clinical ["Trial Studies"](#) since 2007's have clearly proven that clearly demonstrated the importance of training and compliance in securing the most positive outcome for each trial subject over a minimum six-month treatment protocol. The training materials provided by the USPhysioMED main consideration, a qualified and medical, "Traction Therapy Device Program" coupled with the Physicians the manufacturer video-disk and printed manuals, provide enough information for most patients to be able to quickly assemble and apply the device with the proper degree of starting traction to the penis. The manufacturer's recommendation is that the patient begin treatment with mild

traction for a period of four hours per day, with a 20-minute break after the first two hours. This is indicated as a minimum time, with additional time at the patient's discretion. This same protocol was followed during the clinical trial. The compliancy effect at sticking to your Urologist.

Since most of the subjects were from around the United States distant from the trial site in Chicago, patient visits were scheduled once monthly. During the intervening weeks, a phone

call was made to each subject. Initially, this call was intended to track any adverse events or other patient issues well prior to the next visit. As the compliance calls progressed, it was learned that they we're having a psychological impact that was more important to the treatment outcome than simple adverse event tracking as well. This monitoring of subject activity encouraged regular and prolonged daily traction therapy and addressed subject concerns regarding device function or questions on tissue response that were then conveyed to the principle investigator.

It was quickly learned which patients were highly motivated, who were wearing their devices at work and at home for periods of up to eight hours a day, and who

had a sense of confidence about the results. Other patients could be identified as those with less motivation, less confidence in the results, and a corresponding reduction in the actual amount of time given to wearing the device each day.

It was clear when the trial ended, that patient compliance was the critical factor in the degree of positive outcome achieved. Also, that the weekly contact calls played a major role in the overall level of patient compliance.

[A Guide to Peyronie's Disease](#), Current Research & Emerging Treatment were having a psychological impact that was more important to the treatment outcome than simple adverse event tracking. Actual adverse events were not occurring, but the weekly calls, made by one research assistant, became opportunities to identify and address compliance issues, motivation issues and to provide a sense of continuity and involvement for the subjects. This monitoring of subject activity encouraged regular and prolonged daily traction therapy and addressed subject concerns regarding device function or questions on tissue response that were then conveyed to the principle investigator.
